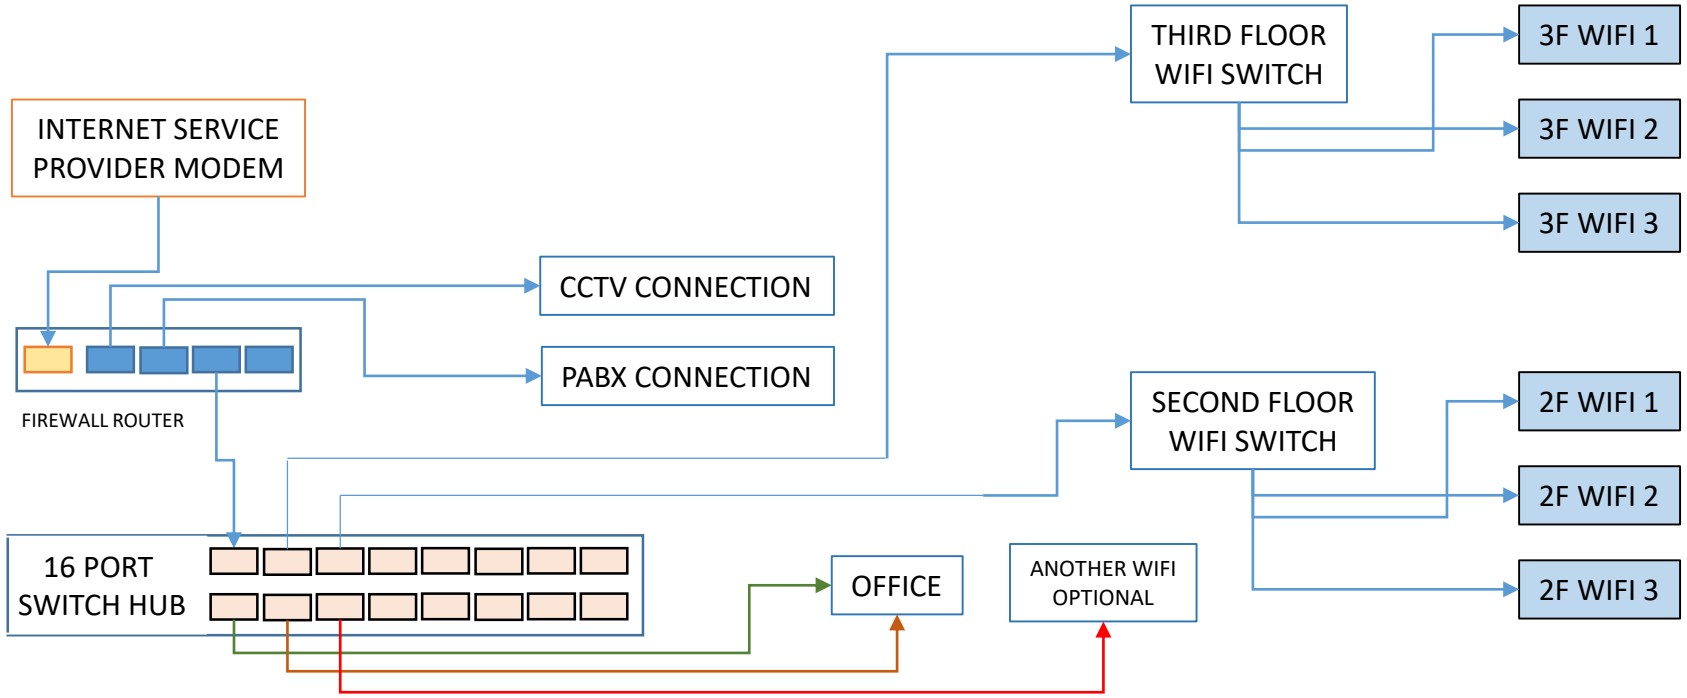
BUSINESS NETWORK SOLUTIONS LAYOUT



FIREWALL ROUTER:

1. Provides Protection from outside attacked or hacking because This router is automatically closed from the inside. And it is Configurable if you want to allow applications to connect to Your network Like VPN and other stuffs.

2. We can use two Internet Service Provider at the same time to Avoid downtime just incase one of the two provider is down due To technical problem or fiber cable cut from the light posts.

3. We can limit bandwidth distributed to a specific network Like Wifi Extender

SWITCH HUB:

1. Distribute internet / data to the computers Or devices that is connected to the network.

INTERNET SERVICE PROVIDER MODEM:
This device is the hardware that connects you outside Network and this is normally Open for attack or hacking That is why need firewall
Normally All Telco Modems allows 6 or 10 connected devices To prevent you from using more bandwidth or the modem will Tell the Server of the telco that there are 6 users connected Then then throttle you connection or they will slow you down

The current layout shows only one is connected, the Firewall Router even if we have 100 users connected behind the firewall

Lets day we don't have the Firewall we cant call our network as private because there is no rules blocking outside traffic
